

IT运维系统

结构：SSM框架+JSP

hlnms-webapp: controller层+视图层

- controller controller 层 --命名: XXXController
- webapp 视图层
 - app 页面
 - resource js脚本 css样式文件 图片等资源
 - WEB-INF/tags 自定义标签

hlnms-service: service层

- api 接口 --命名: XXXServiceAPI
- impl 实现类 --命名: XXXService

hlnms-dao: dao层

- api 接口 --命名: XXXDaoAPI
- resources/mapper 对应Sql xml文件 -命名: -XXXMapper

关系：

- XXXService implements XXXServiceAPI service实现service接口
- XXXService 调用 XXXDaoAPI 进行数据库操作
- XXXDaoAPI 与 -XXXMapper 一一对应 在Mapper中编写Sql语句
- XXXController 控制层调用 XXXService service层实现相关业务

hlnms-probe （重点）

根据不同协议采集各个资源指标

数据表

- md_motype 模型类型表

字段	索引	外键	触发器	选项	注释	SQL 预览					
名					类型	长度	小数点	不是 null	键	注释	
▶ MOTYPEID					decimal	10	0	☒	 1	模型的ID	
MOTYPECODE					varchar	128	0	☒		模型的ID	
MOTYPENAME					varchar	128	0	☒		模型的名称	
ISTOP					varchar	1	0	☒		0 : TOP 1 : SUB	
MOTYPETABLE					varchar	70	0	☒		实例表名 OBJ_MOTYPEID	
CREATEUSER					varchar	64	0	☒		模型的ID	
CREATETIME					datetime	0	0	☒		模型的ID	
UPDATEUSER					varchar	64	0	☐		模型的ID	
UPDATETIME					datetime	0	0	☐		模型的ID	

ISTOP:0表示该模型为顶层对象，1表示子对象

可以根据MOTYPETABLE字段获取该模型下所有资源所在的表 **obj_xxxx**

- **obj_xxxx 资源表** xxx为对应模型类别ID

对象	model_jg @s...	model_jf @s...	model_jg_jf_r...	model_jg_obj...	model_obj_p...	md_motype ...	md_motype ...	md_motype ...	md_test_indic...	obj_10001 @...	cfg_vendor

- 父资源ID
- 父资源类型

每一个模型有其对应的指标集

以Linux服务器为例 该模型有两个指标集 ICMP指标集和SNMP指标集 对应的数据表为md_indicatorset

INDICATORSETID	INDICATORSETCODE	INDICATORSETNAME	MOTYPEID	DATAPERIOD	PROTOCOLID	INDICORTABLE	CREATEUSER	CREATETIME	UPDATEUSER	UPDATE
10023	LinuxServerSNMPSet	Linux Server SNMP Set	10001	300		2 RAW_10023	admin	2018-08-30 10:20:06	admin	2021-10

关键字段：

- INDICATORSETID：指标集ID
- INDICATORSETCODE：指标集编码
- INDICATORSETNAME：指标集名称
- MOTYPEID：所属模型ID
- INDICORTABLE：指标数据所对应的表

指标所在的表为md_indicator

字段：

名	类型	长度	小数点	不是 null	键	注释
INDICATORID	decimal	10	0	☒	1	指标ID
INDICATORCODE	varchar	128	0	☒		指标编码
INDICATORNAME	varchar	128	0	☒		指标名称
MOTYPEID	decimal	10	0	☒		模型ID
INDICATORSTYPE	decimal	1	0	☒		0:KPI 1:COUNTER
INDICATORSETID	decimal	10	0	☒		指标集ID
UNITID	decimal	10	0	☒		单位ID
DISPLAYDECIMAL	varchar	1	0	☒		保留小数点位数
DESCRIPTION	varchar	256	0	☐		描述
COMMAND	varchar	4000	0	☐		采集指标命令
ESCAPE	varchar	256	0	☐		结果转义
RULEID	decimal	10	0	☐		规则ID
CALCULATION	varchar	512	0	☐		计算方式
COLUMNNAME	varchar	10	0	☒		指标对应列名
CREATETIME	datetime	0	0	☒		创建时间
CREATEUSER	varchar	64	0	☒		创建用户
UPDATETIME	datetime	0	0	☐		更新时间
UPDATEUSER	varchar	64	0	☐		更新用户
ISVIEW	varchar	1	0	☐		0:hide 1:view

关键字段：

- INDICATORID：指标ID
- MOTYPEID：模型ID
- INDICATORSTYPE：指标集ID
- COMMAND：采集指标命令（非KPI指标）
- CALCULATION：计算方式（如果是KPI指标，此处存储的是计算规则）
- COLUMNNAME：对应列名（KPI_XX,即该指标在指标采集表中所在的列）

以指标10029（CPU使用率为例）

- 该指标为模型10001（Linux服务器）
- 10023（LinuxServerSNMPSet）指标集中的指标
- 是一个KPI指标 计算公式为 AVG{#[Linux服务器CPU].[Linux Server CPU SNMP Set].[cpu使用率]}
- 在数据表中对应的列为 KPI_1 由指标集可知对应的表为RAW_10023

综合来看就是 Linux服务器模型的 LinuxServerSNMPSet指标集中的 CPU使用率指标 存放在 RAW_10023表的 KPI_1 字段

角色管理:

数据表:

- pms_role 角色表
- pms_role_menu 角色-菜单关联表 **角色ID-菜单ID**
- pms_role_motype 角色-模型关联表 **角色ID-模型ID-对应资源数据表名**
- pms_role_node 角色-资源管理表 **角色ID-资源ID-模型ID**

资源列表功能模块

查询实体列表: getEntityItems () 查询设备级的对象数据, 包含统计子对象数量、过滤条件、分页

参数:

- pageSize: 分页大小
- curPage: 当前页面
- alarmId: 告警状态ID (默认-1) 关联rlt_obj_alarmstatus表
- venderId: 销售公司ID (默认-1) 关联cfg_vendor表
- domainId: 所属域ID (默认-1) 关联cfg_domain表
- motypeld: 模型ID (默认-1)
- searching: 搜索内容 (默认"")

1、PageBounds绑定分页

```
PageBounds pageBounds = new PageBounds(curPage, pageSize);
```

2、根据当前用户获取该用户对应的资源结点, **查找用户资源权限, 返回设备级对象ID**

```
List<String> objIds =  
commonServiceAPI.getResCodeList(Common.getRemoteUser(request));
```

- 2.1如果当前用户为管理员 (userType=1) , 则返回NULL

```
pmsDaoAPI.findUserType(userId) == 1
```

- 2.2 否则根据用户查找结点列表 如果为空插入负值为过滤参数

```
List<String> list = pmsDaoAPI.user_hasNodes(userId);  
if (list.size() == 0)  
{  
    list.add("-888888");  
}
```

- user_hasNodes 根据用户ID 获取其有权限的资源ID
 - 1、根据用户ID查询用户角色, 根据pms_role_node表的关联查找具体资源
 - 2、根据用户ID查询用户角色, 根据pms_role_motype表找到相应的模型ID,再根据rlt_motype_obj找到模型下的资源
 - 3、两者取并集

3、若objIds为null或空, 说明该用户无有权限的资源, 直接返回null, 否则根据资源ID查询具体资源信息

3.1、设置数据源

```
DataSourceContextHolder.setTargetDataSource(DataSourceType.model);
```

3.2、查询所有模型信息,获取对应模型所存的数据表表名

```
List<Map<String, Object>> params = resourceCount.getObjectsMoTables();
```

3.3、若模型不为空,则查询资源信息,参数:分页、用户权限下的资源ID列表、模型列表、搜索内容、告警状态、销售商ID、模型ID、区域ID

```
moinfos = resourceCount.getAllEntitesForCount(pageBounds, objIds, params,
        searching, alarmId, venderId,
        motypeId, domainId);
```

查询所有资源信息: 遍历模型列表,从模型中获取资源所在数据表名 拼接到sql语句中

```
<foreach collection="params" item="item" index="key" separator="union">
    SELECT
        O.OBJID,O.OBJNAME,O.OBJCODE,O.IP,O.MOTYPEID,case when O.VENDORID is null
then 0 else O.VENDORID end as
        VENDORID,O.MODEL,V.VENDORNAME,O.DOMAIN AS DOMAINID,D.DOMAINNAME,
        '${item.MOTYPEPETABLE}' as MOTYPEPETABLE,
        '${item.MOTYPEPENAME}' as MOTYPEPENAME,
        '${item.MOTYPEPECODE}' as MOTYPEPECODE
    FROM
        ${item.MOTYPEPETABLE} O LEFT JOIN cfg_vendor V ON O.VENDORID=V.VENDORID
LEFT JOIN cfg_domain D ON
        O.DOMAIN=D.DOMAINID
</foreach>
```

增加限制条件,查询满足筛选条件的数据:

```
<select id="getAllEntitesForCount" resultType="java.util.HashMap"
parameterType="java.util.Map" databaseId="mysql">
    SELECT
        A.*, CASE OA.ALARMSTATUS WHEN 0 THEN 7 ELSE OA.ALARMSTATUS END AS
        ALARMSTATUS,L.ALARMLEVELCOLOR,L.ALARMLEVELNAME,L.ALARMLEVELRGB
    FROM
        (
        <foreach collection="params" item="item" index="key" separator="union">
            SELECT
                O.OBJID,O.OBJNAME,O.OBJCODE,O.IP,O.MOTYPEID,case when O.VENDORID is null
then 0 else O.VENDORID end as
                VENDORID,O.MODEL,V.VENDORNAME,O.DOMAIN AS DOMAINID,D.DOMAINNAME,
                '${item.MOTYPEPETABLE}' as MOTYPEPETABLE,
                '${item.MOTYPEPENAME}' as MOTYPEPENAME,
                '${item.MOTYPEPECODE}' as MOTYPEPECODE
            FROM
                ${item.MOTYPEPETABLE} O LEFT JOIN cfg_vendor V ON O.VENDORID=V.VENDORID
LEFT JOIN cfg_domain D ON
                O.DOMAIN=D.DOMAINID
        </foreach>
```

```

) A
LEFT JOIN rlt_obj_alarmstatus OA ON A.OBJID = OA.OBJID LEFT JOIN
cfg_alarmlevel L ON
OA.ALARMSTATUS=L.ALARMLEVELID
<where>
  <if test="objIds!=null">
    A.OBJID IN
    <foreach item="item" index="index" collection="objIds" open="("
separator="," close=")">
      #{item}
    </foreach>
  </if>
  <if test="searching!=null">
    <bind name="pattern" value="'%' + searching + '%'" />
    AND (UPPER(OBJNAME) LIKE '${pattern}' OR IP LIKE '${pattern}')
  </if>
  <if test="alarmId!=-1">
    AND ALARMSTATUS=#{alarmId}
  </if>
  <if test="venderId!=-1">
    AND VENDORID=#{venderId}
  </if>
  <if test="motypeId!=-1">
    AND MOTYPEID=#{motypeId}
  </if>
  <if test="domainId==0">
    AND (A.DOMAINID IS NULL OR A.DOMAINID='')
  </if>
  <if test="domainId!=-1 and domainId!=0">
    AND A.DOMAINID=#{domainId}
  </if>
</where>
ORDER BY
ALARMSTATUS ASC,OBJID DESC
</select>

```

4、根据资源ID，查询该资源下子资源的数量

```

for (Map<String, Object> info : moinfos)
{
    long objId = Long.parseLong(info.get("OBJID").toString());
    List<Map<String, Object>> subCounts =
resourceCount.getSubTypeCountOfEntity(objId);
    info.put("subCounts", subCounts);
}

```

根据rlt_motype_obj表中父ID和父类型来分组计数

```

SELECT
    COUNT(MO.MOTYPEID) AS NUM,
    MO.MOTYPEID,
    M.MOTYPENAME,
    M.MOTYPETABLE
FROM rlt_motype_obj MO, md_motype M
WHERE MO.PARENTID = #{objId} AND MO.MOTYPEID = M.MOTYPEID
GROUP BY MO.MOTYPEID, M.MOTYPENAME, M.MOTYPETABLE

```

查询资源下所属子对象信息

getSubEntites ()

参数:

- moTable: 子资源所在的表 (由查询资源列表时返回的subCounts中的MOTYPETABLE确定)
- objId: 资源ID (父资源)
- subMotypeId: 子模型ID
- searching: 搜索条件
- pageSize: 分页大小
- curPage: 当前页
- sortName:
- sortOrder:

新增模型

API: addMoType ()

参数:

- code(moTypeCode) 模型编码
- name(moTypeName) 模型名称
- isTop 0: 顶层对象 1: 子对象
- groupId: 分组Id **md_group**
- parentIds: 父对象Id
- id: 0: 新增
- attrs: 属性(基础属性+自定义属性)
- commonMotypeId: 公共类型 **md_motype_common**

1、增加模型数据以及相关obj_xxx表 addMoTypeModel

参数:

- moTypeCode
- MoTypeName
- isTop
- request

```

HashMap<String, Object> map = new HashMap<>();
    map.put("moTypeCode", moTypeCode);
    map.put("moTypeName", MoTypeName);
    map.put("isTop", isTop);
    map.put("createUser",
com.halu.saber.service.Common.getRemoteUser(request));
    map.put("createtime", new Date());
modelTypeDaoAPI.saveMoType(map);

```

在模型表md_moType中新增一条数据，插入时根据获取到的模型ID，生成相应表名obj_\${id}

```

<selectKey keyProperty="id" resultType="java.lang.Integer" order="BEFORE"
databaseId="oracle">
    select seq_obj_id.nextval id from dual
</selectKey>
<selectKey keyProperty="id" resultType="java.lang.Integer" order="BEFORE"
databaseId="mysql">
    select nextval('SEQ_OBJ_ID')
</selectKey>

insert into Md_Motype
(motypeid,motypecode,motypename,ISTOP,motypetable,createuser,createtime)
values ({id}, #{moTypeCode},#{moTypeName},#{isTop},'obj_${id}',#
{createUser},#{createtime})

```

根据模型编码获取模型ID，生成obj_xxx表 createObjTable(MoTypeId, request);

首先判断obj_xxx表是否存在，若不存在，则动态生成属性列：

```

if (exist == 0)
{
    List<String> columns = new ArrayList<String>();

    // 添加动态属性
    for (int i = 2; i <= COLUMNS_COUNT; i++)
    {
        String att = ATTRIBUTE + i;
        columns.add(att);
    }
    tableParam.put("columns", columns);
}

```

参数：

```

// 表名前缀
private static final String OBJ_TABLE = "OBJ_";
// 属性列前缀
private static final String ATTRIBUTE = "Att_";
// 列数量
private static final int COLUMNS_COUNT = 50;

```

2、如果groupId不为空 保存模型与分组之间的联系 (即在 rlt_motype_group 表中新增数据)

```
HashMap<String, Object> map = new HashMap<>();
map.put("motypeId", id);
map.put("groupId", groupId);

modelTypeDaoAPI.saveMotypeGroup(map);
```

3、如果该模型有父类型 parentId不为空 增加两者之间的关联 (addMoRelation(parentIds, motypeCode, request);)

在rlt_motype_motype表中插入数据

字段:

- MOTYPEID 模型ID
- PARENTMOTYPEID 父模型ID

4、如果有公共模型 commonMotypeId不为空 增加两者之间的关联 (modelTypeDaoAPI.saveMotypeCommon(map);)

在rlt_commonmotype_motype中插入数据

字段:

- MOTYPEID 模型ID
- COMMONMOTYPEID 公共模型ID

5、如果属性不为空 attrs不为空，为模型增加属性

attrs:

- 基础属性 (根据公共模型确定?)
- 自定义属性

数据结构: {"attrName":"属性1","unit":"","comAttrName":"*"}

- attrName: 属性名
- unit: 单位 (为空表示为text)
- comAttrName: 基础属性 (自定义属性为*)

方法: addMoAttribute(attrs, id, request, attributeMap);

参数:

- attrs: 前端传入的属性 (JSON)
- id: 模型ID
- request: 请求
- attributeMap: 在新增模型时空

addMoAttribute(attrs, id, request, attributeMap)

- 对数据进行处理 放入HashMap中

```

HashMap<String, Object> map = new HashMap<>();
map.put("attributeName", attributeJson.get("attrName"));
map.put("moTypeId", moTypeId);
map.put("createUser", com.halu.saber.service.Common.getRemoteUser(request));
map.put("createtime", new Date());
// 判断属性的单位是否为空，如果为空则为text，数据库保存为null
if (!ObjectUtils.isEmpty(attributeJson.get("unit")))
{
    map.put("attributeUnit1", attributeJson.get("unit"));
}

```

- 获取当前模型属性列数组 (modelTypeDaoAPI.getUserATTNum(moTypeId))

```

select replace(t.columnname,'ATT_', '') as NUM from md_moattribute t where
t.motypeid=#{_parameter}

```

- 在md_moattribute表插入数据

```

if (!ATTCount.contains((i + 1) + ""))
{
    map.put("columnName", "ATT_" + (i + 1)); //在obj_xxx 中该属性对应于那一列
    // 判断之前是否存在该属性，若存在，则保留原属性ID
    if (!ObjectUtils.isEmpty(attributeMap.get(map.get("attributeName"))))
    {
        map.put("id", attributeMap.get(map.get("attributeName")));
        modelTypeDaoAPI.insertMoAttribute(map);
    }
    else
    {
        modelTypeDaoAPI.saveMoAttribute(map);
    }
}

```

- 如果为基础属性，需要插入属性与公共属性的关联关系 rlt_commonattribute_attribute

字段：

- MOTYPEID 模型ID
- ATTRIBUTEID 属性ID
- COMMONATTRIBUTEID 公共属性ID

```

if (!"*".equals(attributeJson.get("comAttrName")))
{
    // 校验没有问题开始插入数据
    map.put("commonAttributeName", attributeJson.get("comAttrName"));
    Map<String, Object> commonAttributeMap =
modelTypeDaoAPI.getCommonAttributeMap(map);
    String commonAttributeId =
String.valueOf(commonAttributeMap.get("COMMONATTRIBUTEID"));
    // 判断属性是否存在
    String attributeID = modelTypeDaoAPI.getAttrIdByNameAndModelType(map);
    map.put("attributeId", attributeID);
    map.put("commonAttributeId", commonAttributeId);
    modelTypeDaoAPI.insertRltComattrAttr(map);
}

```

新增指标

```
addIndicator(IndicatorModel indicatorModel, HttpServletRequest request)
```

参数:

- indicatorid 指标id, 为0时表示新增, 否则为更新指标
- indicatorcode 指标编码
- indicatorsetid 指标集编码
- motypeid 模型ID
- indicatortype 指标类型 0:KPI指标 1:普通指标
- isView 是否显示

md_indicator

如果是公共指标 需要增加两者之间的联系 **rlt_commonindicator_indicator**

```

// 数据库变动时通知后台 根据探针类型给探针发送消息
commonServiceAPI.sendMessageToProbe(ProbeType.Performance,
ProbeCommandName.update);

```

```

//枚举类
public enum ProbeType {
    Discover, Configuration, Performance, Dial, Event, Inspect, ConfigFile,
    Process,vmware
}

public enum ProbeCommandName {
    start, stop, update, updateConfigs, status, realTime, realTimeConnect
}

```

sendMessageToProbe

1、根据探针类型 获取探针列表 collect_probe

```
List<String> probeIds = common.getProbeList(probeType.name());
```

指标采集任务：

使用Quartz来作为解决任务调度的工具（相较于Timer 可以处理复杂逻辑调度和类似于每个星期一12: 00处理任务）

结构：

- **Job接口**：这个方法定义了需要调度的方法，开发者在使用Quartz并定义调度任务时候，需要实现这个接口并且重写此方法。

```
public interface Job {  
    void execute(JobExecutionContext var1) throws JobExecutionException;  
}
```

在本项目中使用JobImpl来实现该接口

```
public class JobImpl implements Job  
{  
    private static final Logger logger = LoggerFactory.getLogger(JobImpl.class);  
  
    @Override  
    public void execute(JobExecutionContext context) throws  
JobExecutionException  
    {  
        //需要进行调度执行的任务  
        TaskManager.getInstance().executeTask();  
    }  
}
```

- **JobDetail** JobDetail表示一个具体的可执行的调度程序，Job是这个可执行调度程序所要执行的内容，另外JobDetail还包含了这个任务调度的方案和策略

```
JobDetail jobDetail = JobBuilder  
    .newJob(JobImpl.class)    //所要执行的内容 即job的实现类  
    .withIdentity("collectTask", Scheduler.DEFAULT_GROUP) //分  
组标识  
    .build();
```

- **Trigger** 触发器 主要是触发Job执行的时间触发规则
 - SimpleTrigger
 - CronTrigger

CronTrigger 支持类似日历的重复间隔，而不是单一的时间间隔。

```
// 触发器
TriggerBuilder<Trigger> triggerBuilder = TriggerBuilder.newTrigger();
// 触发器名,触发器组
triggerBuilder.withIdentity("collectTaskTrigger", Scheduler.DEFAULT_GROUP);
triggerBuilder.startNow();
// 触发器时间设定
triggerBuilder.withSchedule(CronScheduleBuilder.cronSchedule(taskPeriodStr));
// 创建Trigger对象
CronTrigger trigger = (CronTrigger) triggerBuilder.build();
```

- 通过triggerBuilder.build 来获得一个触发器实例
- 可以通过triggerBuilder来设置触发器属性 如触发器组、触发器时间等
- triggerBuilder.withSchedule() 设置触发时间 传入的是 CronScheduleBuilder.cronSchedule(taskPeriodStr)
- CronScheduleBuilder.cronSchedule(taskPeriodStr) taskPeriodStr为cron表达式 表示执行的时间间隔

◦ ProbeTaskQuartz=0 0/5 * * * ? //每5分钟执行一次

- **Scheduler**代表一个Quartz的独立运行容器，Trigger和JobDetail可以注册到Scheduler中，二者在Scheduler中有各自的组件、名称和组

```
scheduler.scheduleJob(jobDetail, trigger);
```

Scheduler可以将Trigger绑定到某一个JobDetail上，当Trigger被触发时，对应的Job就被执行，一个Job可以对应多个Trigger，一个Trigger只能对应一个Job，

```
scheduler.start();
```

启动执行

每过5分钟后就会执行TaskManager.getInstance().executeTask()方法

- TaskManager.getInstance() 获得一个TaskManager的单例对象
- .executeTask()执行该对象下的executeTask方法

执行采集任务 executeTask () (snmp协议)

1、首先根据配置文件获取探测任务周期(默认为300秒 即5分钟)

```
String taskPeriodStr = ProbeContextHolder.getStringValue("ProbeTaskPeriod");
long taskPeriod = 300;
if (!ObjectUtils.isEmpty(taskPeriodStr) && ObjectUtils.isNumber(taskPeriodStr))
{
    taskPeriod = Long.parseLong(taskPeriodStr);
}
```

ProbeContextHolder 根据不同的探针类型读取相应的配置文件 在探针启动时读取相应的配置文件

ProbeContextHolder.getStringValue("ProbeTaskPeriod"); 获取配置文件 **core.properties** 中 **ProbeTaskPeriod**对应的值

2、获取任务开始时间

```
long nowTime = System.currentTimeMillis();
Date startTime = new Date(nowTime - nowTime % (taskPeriod * 1000)); //格式化时间
去除偏差 精确到 00秒
```

3、获取需要进行采集的对象列表

采集对象的操作基本都通过**ObjectManager**类来进行操作

```
List<ObjectModel> objectModelList = objectManager.getObjectList(
    ProbeContextHolder.getStringValue(Constants.PROBE_PROTOCOL),
    System.getProperty(Constants.PROBE_ID));
```

objectManager.getObjectList (String protocol, String probeId)

参数:

- protocol 探针采集协议此处值为 ("SNMP")
 - **Constants.PROBE_PROTOCOL** 常量 ProbeProtocol
 - 即 ProbeContextHolder.getStringValue ("ProbeProtocol")
 - `ProbeProtocol=SNMP`
- probeId 探针ID 值为 ("Probe-Perf-SNMP")
 - **Constants.PROBE_ID** 常量 **probe.id**
 - 即 System.getProperty("probe.id")

(1) 根据 probeId 探针ID获取各个模型及其对应协议下的指标集以及属性

md_motype 根据 MOTYPEID关联 **md_indicatorset**

md_indicatorset 根据指标集ID关联 **md_indicatorass**

从**collect_probe**表和**cfg_protocol**表中获取对应的协议ID **protocolid**进行筛选

Probe-Perf-SNMP 对应的协议为 SNMP 对应的协议ID为 2

返回数据结构如下:

```
> this = {ObjectManager@3566}
> protocol = "SNMP"
> probeId = "Probe-Perf-SNMP"
> indicatorTypeList = {ArrayList@3722} size = 95
  > 0 = {LinkedCaseInsensitiveMap@3724} size = 7
    > "MOTYPEID" -> {BigDecimal@3831} "10001"
    > "INDICATORSETID" -> {BigDecimal@3833} "10023"
    > "ASSTYPE" -> "0"
    > "ATTRIBUTEID" -> null
    > "OPER" -> null
    > "VALUE" -> null
  > 1 = {LinkedCaseInsensitiveMap@3725} size = 7
  > 2 = {LinkedCaseInsensitiveMap@3726} size = 7
  > 3 = {LinkedCaseInsensitiveMap@3727} size = 7
```

(2) 遍历上方集合 如果 根据协议ID、探针ID、资源表名获取所有对象

```
allObjList = performanceDao.getObjectForAll(protocol, probeId, motypetable);
```

数据表:

- obj_xxx 资源实体表
- collect_credential 采集凭证表
- rlt_credentials_obj 采集凭证-资源联系表

限制条件:

- OBJ.ISCOLLECTION = 1 资源是否采集标志位为 1
- 资源凭证的协议ID

```
(SELECT PROTOCOLID
FROM CFG_PROTOCOL
WHERE PROTOCOLNAME = ?)
AND OBJ.OBJID IN
( SELECT MO.OBJID FROM rlt_motype_obj MO , collect_probe P WHERE MO.SERVERID =
P.SERVERID AND P.PROBEID = ?)
```

SERVERID 作用暂不清楚

返回字段:

- 资源ID
- 资源名称
- 资源IP
- 凭证ID
- 凭证名称
- 凭证参数

```
ObjectModelMap = (HashMap@4764) size = 1
  4087479 -> (ObjectModel@5111) "ObjectModel[objId='4087479', objectName='后台管理服务器', ip='192.168.0.167']"
    key = "4087479"
    value = (ObjectModel@5111) "ObjectModel[objId='4087479', objectName='后台管理服务器', ip='192.168.0.167']"
      indicatorSetIdList = (ArrayList@5148) size = 1
        objId = "4087479"
        objectName = "后台管理服务器"
        moTypeId = "10001"
        ip = "192.168.0.167"
        credential = (HashMap@4921) size = 6
          port -> (char[3]@4959) [1, 6, 1]
          snmpVersion -> (char[3]@4969) [v, 2, c]
          ip -> (char[13]@4944) [1, 9, 2, ., 1, 6, 8, ., 0, ., +3 more]
          credentialId -> (char[5]@4946) [1, 0, 0, 0, 1]
          credentialName -> (char[14]@4948) [S, N, M, P, ., p, u, b, l, i, +4 more]
          community -> (char[6]@5106) [p, u, b, l, i, c]
          SubIndicatorSetModelList = null
```

遍历objectModelList，为objModel加载所有的子对象指标集SubIndicatorSetModelList：

```
getObject(objectModel, objectModel.getMoTypeId(), objectModel.getObjId());
```

- 根据模型id moTypeId 获取所有子模型ID
- 根据子模型ID获取对象的指标集列表
- 遍历获取模型下的子资源
- 将处理后的数据存入SubIndicatorSetModelList列表

最终结果：

```
objectModelList = (ArrayList@5154) size = 24
  0 = (ObjectModel@5111) "ObjectModel[objId='4087479', objectName='后台管理服务器', ip='192.168.0.167']"
    indicatorSetIdList = (ArrayList@5148) size = 1
      0 = "10023"
      objId = "4087479"
      objectName = "后台管理服务器"
      moTypeId = "10001"
      ip = "192.168.0.167"
      credential = (HashMap@4921) size = 6
        port -> (char[3]@4959) [1, 6, 1]
        snmpVersion -> (char[3]@4969) [v, 2, c]
        ip -> (char[13]@4944) [1, 9, 2, ., 1, 6, 8, ., 0, ., +3 more]
        credentialId -> (char[5]@4946) [1, 0, 0, 0, 1]
        credentialName -> (char[14]@4948) [S, N, M, P, ., p, u, b, l, i, +4 more]
        community -> (char[6]@5106) [p, u, b, l, i, c]
    SubIndicatorSetModelList = (ArrayList@5430) size = 5
      0 = (SubIndicatorSetModel@5432)
        indicatorSetId = "10025"
        entityList = (ArrayList@5438) size = 2
          0 = (SubObjectModel@5440)
            objId = "4087481"
            objectName = "192.168.0.167_LinuxServerInterface_1"
            moTypeId = "10002"
            index = "1"
          1 = (SubObjectModel@5441)
            objId = "4087482"
            objectName = "192.168.0.167_LinuxServerInterface_2"
            moTypeId = "10002"
            index = "2"
        1 = (SubIndicatorSetModel@5433)
        2 = (SubIndicatorSetModel@5434)
        3 = (SubIndicatorSetModel@5435)
        4 = (SubIndicatorSetModel@5436)
      1 = (ObjectModel@5380) "ObjectModel[objId='4088767', objectName='192.168.0.168', ip='192.168.0.168']"
      2 = (ObjectModel@5382) "ObjectModel[objId='4086489', objectName='192.168.0.254', ip='192.168.0.254']"
      3 = (ObjectModel@5384) "ObjectModel[objId='4088768', objectName='192.168.0.169', ip='192.168.0.169']"
      4 = (ObjectModel@5386) "ObjectModel[objId='4088758', objectName='192.168.0.101', ip='192.168.0.101']"
```

(4) 获取到objectModelList后循环遍历

- 根据 objectModel.getIndicatorSetIdList() 中的指标集 获取相应指标模型
- 根据指标模型获取采集时间间隔，过滤掉不在时间间隔内的数据

```

IndicatorSetModel indicatorSetModel =
IndicatorsManager.indicatorSetModelMap.get(indicatorSetId);
long period = Long.parseLong(indicatorSetModel.getDataPeriod());
IndicatorSetModel indicatorSetModel =
IndicatorsManager.indicatorSetModelMap.get(indicatorSetId);
long period = Long.parseLong(indicatorSetModel.getDataPeriod());

```

- 对子资源的指标集进行相同过滤
- 获得符合时间间隔的采集对象 objMap
- 遍历objMap 生成采集任务实体列表

```

List<TaskModel> taskList = new ArrayList<>();
for (Map.Entry<String, ObjectModel> entry : objectMap.entrySet())
{
    TaskModel taskModel = new TaskModel(startTime);
    taskModel.setRootObjectModelList(new ArrayList<>());
    taskModel.getRootObjectModelList().add(entry.getValue());
    taskList.add(taskModel);
}

```

- startTime 任务开始时间
- rootObjectModelList 被管对象信息列表

```

taskList = (ArrayList@6265) size = 24
0 = (TaskModel@6270) *TaskModel[, startTime=Tue Mar 22 11:50:00 CST 2022]*
  startTime = (Date@3562) *Tue Mar 22 11:50:00 CST 2022*
  fastTime = 1647921000000
  cdate = (GregorianCalendar@6298) *2022-03-22T11:50:00.000+0800*
  rootObjectModelList = (ArrayList@6296) size = 1
    0 = (ObjectModel@5666) *ObjectModel(objId='4087479', objectName='后台管理服务器', ip='192.168.0.167')*
      objId = '4087479'
      objectName = '后台管理服务器'
      moTypeld = '10001'
      ip = '192.168.0.167'
      credential = (HashMap@4921) size = 6
        port -> (char[3]@6319) [1, 6, 1]
        snmpVersion -> (char[3]@6321) [v, 2, c]
        ip -> (char[13]@6323) [1, 9, 2, ., 1, 6, 8, ., 0, ., +3 more]
        credentialId -> (char[5]@6325) [1, 0, 0, 0, 1]
        credentialName -> (char[14]@6327) [S, N, M, P, ., p, u, b, l, i, +4 more]
        community -> (char[6]@6329) [p, u, b, l, i, c]
      indicatorSetIdList = (ArrayList@5703) size = 1
        0 = '10023'
      SubIndicatorSetModelList = (ArrayList@5704) size = 5
        0 = (SubIndicatorSetModel@5432)
          indicatorSetId = '10025'
          entityList = (ArrayList@5438) size = 2
            0 = (SubObjectModel@5440)
              objId = '4087481'
              objectName = '192.168.0.167_LinuxServerInterface_1'
              moTypeld = '10002'
              index = '1'
            1 = (SubObjectModel@5441)
              1 = (SubIndicatorSetModel@5433)
              2 = (SubIndicatorSetModel@5434)
              3 = (SubIndicatorSetModel@5435)
              4 = (SubIndicatorSetModel@5436)
        1 = (TaskModel@6271) *TaskModel[, startTime=Tue Mar 22 11:50:00 CST 2022]*
        2 = (TaskModel@6272) *TaskModel[, startTime=Tue Mar 22 11:50:00 CST 2022]*
        3 = (TaskModel@6273) *TaskModel[, startTime=Tue Mar 22 11:50:00 CST 2022]*
        4 = (TaskModel@6274) *TaskModel[, startTime=Tue Mar 22 11:50:00 CST 2022]*
        5 = (TaskModel@6275) *TaskModel[, startTime=Tue Mar 22 11:50:00 CST 2022]*

```

```
TaskQueue.getInstance().commit(taskList);
```

遍历采集对象，开启一个新的线程放入线程池中来来进行采集任务

```
ListenableFuture<FutureModel> future =  
    ThreadPoolManager.getInstance().submit(new TaskThread(rootObjectModel,  
taskModel.getStartTime()));
```

任务线程:

```
public TaskThread(ObjectModel rootObjectModel, Date startTime)  
{  
    this.rootObjectModel = rootObjectModel;  
    this.startTime = startTime;  
}
```

传入参数:

- 采集对象
- 任务开始时间

线程调用**ProbeExecutor**协议采集实现实例 通过**executeTask ()** 方法来进行采集任务

```
ProbeExecutor t = null;  
// 执行一个顶层对象的任务  
try  
{  
    t = new ProbeExecutor();  
    return t.executeTask(rootObjectModel, startTime);  
}
```

executeTask () 采集任务

1、连接

- 获取采集实现类 即**ICollector**接口的实现类 (snmp协议的实现类为**SnmpCollectorImpl**)

```
// 获取采集实现类  
collect = (ICollector) ProbeContextHolder.getBean("collector");
```

- 连接需要被采集的设备, 返回连接结果

```
// 连接被管对象,传入凭证信息  
collect.connect(rootObjectModel.getCredential());
```

connect:

(1) 校验传入的采集凭证格式, 如果有问题则抛出异常, 没问题则返回一个采集凭证实体对象

```
snmpCredential sc = this.checkSnmpCredential(credentials);
```

(2) 传入当前时间和超期时间，新建一个Snmp协议客户端工具进行连接（如果配置文件中没有超期时间则默认为3分钟）

```
snmpClient = new SnmpClient(new Date(), collectTimeOut);
```

利用客户端工具进行连接

```
isConnect = snmpClient.connect(sc);
```

2、连接成功后进行采集和计算

利用指标采集方法类 **CollectManager**进行采集 返回**ResultModel**

```
ResultModel resultModel = collectManager.collectAndCalculate(rootObjectModel, collect, startTime, isConnect);
```

传入参数：

- rootObjectModel 被管对象
- collect 采集实现类
- startTime 开始时间
- isConnect 是否进行连接

collectAndCalculate:

(1) 采集设备指标

- 遍历**indicatorSetIdList**指标集 获取采集结果模型

```
ResultObjectModel resultObjectModel = getResultObjectModel(indicatorSetId, rootObjectModel.getObjId(), null, collect, isConnect, startTime, valuesMap, logMap);
```

getResultObjectModel

```
private ResultObjectModel getResultObjectModel(String indicatorSetId, String
objId, String index,
        ICollector collect, boolean isConnect, Date starTime, Map<String,
Map<String, Double>> valueCacheMap,
        Map<String, String> logMap)
```

传入参数:

- indicatorSetId 指标集ID
- rootObjectModel.getObjId() 模型ID
- index
- collect 采集实现对象
- isConnect 是否连接
- starTime 开始时间
- valueCacheMap 结果缓存集
- logMap 日志

1、根据指标集ID获取指标集对象

```
IndicatorSetModel indicatorSetModel =
IndicatorsManager.indicatorSetModelMap.get(indicatorSetId);
```

2、遍历指标集内的指标对象，生成对应的KEY

```
String valueCacheKey = "[" + indicatorSetModel.getMoTypeName() + "]" + "." + "[" +
        + indicatorSetModel.getIndicatorSetName() + "]" + "." + "[" +
indicatorModel.getIndicatorName() + "];
```

例如: [Linux服务器].[Linux Server SNMP Set].[文件系统使用率]

如果是普通指标 即type为1 则进行采集

```
collectResult = collect.collect(indicatorModel.getCommand(), index);
```

如果是KPI指标，则先存入计算公式

```
▼ valueMap = (HashMap@6082) size = 4
  > KPI_1 -> (IndicatorModel@6092)
  > KPI_2 -> (IndicatorModel@6119)
  ▼ KPI_3 -> (IndicatorModel@6152)
    > key = "KPI_3"
    ▼ value = (IndicatorModel@6152)
      > IndicatorId = "10031"
      > IndicatorName = null
      > command = null
      > indicatorType = "0"
      > rule = null
      > escape = null
      > calculation = "AVG([Linux服务器文件系统],[Linux Server File System SNMP Set],[已使用簇的个数]*100/[Linux服务器文件系统],[Linux Server File System SNMP Set],[簇的总个数])"
      > column = null
      > value = null
  ▼ KPI_4 -> (IndicatorModel@6184)
    > key = "KPI_4"
    ▼ value = (IndicatorModel@6184)
      > IndicatorId = "10032"
      > IndicatorName = null
      > command = null
      > indicatorType = "1"
      > rule = null
      > escape = null
      > calculation = null
      > column = null
      > value = "0.0"
  > indicatorModel = (IndicatorModel@6327)
```
